Abstract. We present high-resolution optical and near-infrared *HST* observations of two adjacent regions in the fossil starburst region in M82, M82 B1 and B2. The presence of both the active and the fossil starburst in M82 provides a unique physical environment to study the stellar and dynamical evolution of star cluster systems. The cluster population in B2 is more heavily affected by internal extinction than that in B1, amounting to an excess extinction in B2 of $A_{V,\text{excess}} \simeq 1.1 \pm 0.3$ mag. Preliminary age estimates date the cluster population in the fossil starburst between $\sim 2 \times 10^8$ and $\sim 10^9$ years. The radial luminosity profiles of the brightest clusters are more closely approximated by power laws than by a Gaussian model, in particular in their wings, which favors a slow star formation scenario.

Keywords: galaxies: evolution, galaxies: individual (M82), galaxies: photometry, galaxies: starburst, galaxies: star clusters, galaxies: stellar content

1. M82, the prototypical starburst galaxy

Observations at all wavelengths from radio to X-rays are consistent with a scenario that tidal interactions between M82 and another member galaxy of the M81 group has channeled large amounts of gas into the central regions of M82 during the last several 100 Myr (e.g., Telesco 1988, Rieke et al. 1993). This has induced a starburst which has continued for up to about 50 Myr. All of the bright radio and infrared sources associated with the active starburst are confined to the galaxy's center, lying within a radius of ~ 500 pc, and corresponding spatially with bright optical structures, labeled M82 A, C, and E in O'Connell & Mangano (1978, OM78).

However, evidence exists that this is not the only major starburst episode to have occurred in M82. A region at about 1 kpc NE from the galactic center, M82 B (cf. OM78), has exactly the properties one would

^{*} Based on observations with the NASA/ESA *Hubble Space Telescope*, obtained at the Space Telescope Science Institute, which is operated by the Association of Universities for Research in Astronomy (AURA), Inc., under NASA contract NAS 5-26555.

predict for a fossil starburst with a similar amplitude to the active burst. Marcum & O’Connell (1996) find a sharp main-sequence cut-off of the composite stellar system in M82 B, corresponding to an age of $\sim 100\text{--}200$ Myr and an average extinction of $A_V \sim 0.6$ mag. Region A, on the other hand, is only consistent with a very young population (~ 5 Myr) and is more heavily affected by extinction ($A_V \sim 2.2$ mag). By extrapolating region B’s surface brightness ($\mu_V \sim 16.5$ mag arcsec $^{-2}$ [OM78], after correction for foreground extinction) back to an age of 10 Myr we estimate that its surface brightness was ~ 2 magnitudes brighter (cf. the Bruzual & Charlot [1996, BC96] stellar population models), similar to that presently observed in the active starburst.

HST imaging of the bright central regions of M82 resolved these into a swarm of young star cluster candidates, with a FWHM of ~ 3.5 pc ($0.''2$) and mean $L_V \sim 4 \times 10^6 L_\odot$ (O’Connell et al. 1994, 1995), brighter than any globular cluster in the Local Group.

This is the nearest rich system of such objects; such “super star clusters” have also been discovered with *HST* in other interacting and amorphous systems, and in dwarf and starburst galaxies (e.g., Holtzman et al. 1992, Whitmore et al. 1993, O’Connell et al. 1994, Conti et al. 1996, Ho 1997, Carlson et al. 1998, Watson et al. 1998, among others). Their diameters, luminosities, and – in several cases – masses are consistent with these being young *globular* clusters formed as a result of recent gas flows (e.g., van den Bergh 1995, Meurer 1995, Ho & Filippenko 1996). It is possible that most of the star formation in starbursts takes place in the form of such concentrated clusters. Our observations of M82 do not reveal similar cluster formation outside the active and the fossil starburst regions.

Under the assumption that region B is indeed a fossil starburst site, it is expected that it originally contained a complement of luminous clusters similar to that now observed in region A. The combination of observations of both the active and the fossil starburst sites in M82 therefore provides a unique physical environment for the study of the stellar and dynamical evolution of these star cluster systems.

2. *HST* observations of the M82 central region

The fossil starburst region, M82 B, was observed on September 15, 1997, with both *WFPC2* and *NICMOS* on board the *HST*. We imaged two adjacent $\sim 35''$ square fields (Planetary Camera [PC] field of view, $0.''0455$ pix $^{-1}$) in the M82 B region in the F439W, F555W and F814W passbands, with total integration times of 4400s, 2500s and 2200s, respectively, for region “B1”, and 4100s, 3100s and 2200s, respectively,

for region “B2”. These observations were obtained using four exposures per filter, covering a large range in integration times to facilitate the removal of cosmic ray events. The F439W, F555W and F814W filters have roughly similar characteristics to the Johnson-Cousins broad-band B , V and I filters, respectively.

In the near-infrared (NIR) we chose to use *NICMOS* Camera-2 ($0.''075 \text{ pix}^{-1}$), which provided the best compromise of resolution and field of view. We acquired 4 partially spatially overlapping exposures in both the F110W and F160W filters (approximately similar to the Bessell J and H filters, respectively) in a tiled pattern; the integrations, of 512s each, were taken in MULTIACCUM mode to preserve dynamic range and to correct for cosmic rays.

3. Selection procedure

3.1. SELECTION OF REAL SOURCES IN A HIGHLY DISTURBED AREA

Unfortunately, the separation of real sources from artefacts in M82 B is problematic, due to significant small-scale variations in the amplitude of the background emission, which are largely caused by the highly variable extinction. For this reason, we cannot use standard unsharp masking techniques to remove this background, since this produces significant residual emission along the dust features.

An initial visual examination of the multi-passband observations revealed a multitude of faint point sources that become increasingly obvious with increasing wavelength. To include in our source selection a maximum number of real and a minimum amount of spurious sources (due to, e.g., dust features, weak cosmic rays, or poisson noise in regions of high surface brightness or at the CCD edges), we decided to cross correlate source lists obtained in individual passbands. We performed extensive checks to find the best selection criteria and thus to minimize the effects introduced by artefacts on the one hand and the exclusion of either very red or very blue sources on the other.

We chose our detection thresholds such that the number of candidate sources selected from the images in all passbands were comparable, of order 4000. Then, we cross correlated the source lists obtained in the individual passbands. Finally, we determined which combination of passbands resulted in the optimal matching of sources detected in both the blue and the NIR passbands. This source selection procedure lead us to conclude that a final source list obtained from the cross correlation of the candidate sources detected in the F555W and F814W filters would contain the most representative fraction of the M82 B-region source population.

However, an initial visual examination of the cross-correlated V and I -band sources showed that the automated detection routine had returned non-detections as well as artefacts that were clearly associated with dust features. It also showed that the quality of the resulting sources for photometric follow-up was highly variable. Therefore, we decided to check the reality of all cross-correlated sources by examining them visually, in both passbands, at the same time classifying them in terms of contrast, sharpness, and the presence of nearby neighbors. Moreover, we added (and verified) the $\sim 30\%$ of the sources in each field that were missed by the automated detection routine, but were clearly real sources, and were recognized as such by the visual examination of both the V and the I -band images.

The final source lists thus obtained contain 737 and 642 verified sources in M82 B1 and B2, respectively.

3.2. SYNTHETIC AND OBSERVED STAR FIELDS AS CONTROL FIELDS

We estimated the completeness of our object list by randomly and uniformly adding 500 synthetic point sources of input magnitudes between 20.0 and 25.0 mag to the observed images in both the F555W and the F814W filters. The PSFs of the synthetic point sources were obtained from observational PSFs, and scaled to the desired magnitudes. The effects of crowding in our simulated star fields are small: only $\sim 1\text{--}2\%$ of the simulated objects were not retrieved due to crowding or overlap of adjacent sources.

For the uniformly distributed simulated sources, we established the 50% completeness limits at F555W > 23.1 and 23.3 mag (for B1 and B2, respectively) and at F814W > 23.0 mag.

In addition to these synthetic star fields, we used our ω Cen *HST* observations in the F555W passband, obtained as part of program 6053 (PI O’Connell, Cycle 5), to verify the reduction procedures and the accuracy of our photometry.

3.3. SEPARATING STAR CLUSTERS FROM STARS

We based the distinction between stars and more extended sources in the M82 B fields on the statistical differences between the size characteristics of the populations of real sources in these fields and those of the stars in the ω Cen control field. To do so, we added a scaled version of the ω Cen field to the M82 B fields, such that the output magnitudes of the majority of the ω Cen stars were in the same magnitude range as those of the M82 B sources, in the latter reference frame.

We determined characteristic sizes of both our M82 B verified sources and the ω Cen stars, using a Gaussian fitting routine. Although the

true luminosity profiles of the star clusters in M82 B may differ from Gaussians (Sect. 5), this method allows us to distinguish between compact and extended sources. A comparison between the distribution of characteristic stellar sizes from the globular cluster field with those of the verified sources in M82 B revealed that the population of extended sources in M82 B is well-represented by sources with $\sigma_{\text{Gaussian}} \geq 1.25$ pixels. Therefore, in the following we will consider those sources with $\sigma_{\text{G}} \geq 1.25$ and V -band magnitude brighter than the 50% completeness limit to be part of our verified cluster samples. They contain 128 and 218 cluster candidates in B1 and B2, respectively.

4. Stellar population synthesis: tracing the evolution

A close examination of the color distributions in both fields reveals that the cluster population in B2 displays a peak at redder colors, whereas the dispersion in colors is larger than in the B1 region, in particular on the redward side. Both these observations hint at a more heavily obscured globular cluster population in B2. Under the assumption that the candidate cluster populations in B1 and B2 are coeval, which is likely if they originated in the same starburst, the differences between their color distributions can entirely be attributed to extinction effects, amounting to an excess extinction in B2 of $A_{V,\text{excess}} \sim 1.1 \pm 0.3$ mag.

Their color-magnitude diagrams (CMDs) reveal that the brightest young cluster candidates have approximately identical colors and magnitudes in either region: $(B - V)_0 \approx 0.6 \pm 0.2$, $(V - I)_0 \approx 1.0 \pm 0.2$ mag, and $17.5 \lesssim V \lesssim 19.5$; this indicates that these are mainly unaffected by extinction.

We take as tentative color limits for the determination of the intrinsic age spread in the M82 B cluster population $0.2 \pm 0.1 \lesssim (B - V)_{0,c} \lesssim 0.6 \pm 0.2$ and $0.4 \pm 0.2 \lesssim (V - I)_{0,c} \lesssim 1.0 \pm 0.2$. The limits on the blue side are set by the colors of the bluest cluster candidates; the red limits are the colors of the brightest (supposedly unobscured) clusters in either field, since from this color range, most cluster colors can be achieved with up to 2(–3) magnitudes of visual extinction, which is not an unreasonably large amount, considering the highly variable extinction features seen in the images. Employing the BC96 initial burst models yields ages between $\sim 2 \times 10^8$ and $\sim 1 \times 10^9$ yr, assuming solar metallicity. From the optical–near-infrared color-color diagrams shown in Fig. 1, we derive a lower limit to the allowed age range for the bulk of the cluster population of 200–300 Myr, entirely consistent with the age estimates obtained from the optical CMDs.

Figure 1. Optical and NIR color-color diagrams for the cluster candidates in M82 B1 and B2, divided in magnitude bins (roughly corresponding to quality bins); solid dots: $V \leq 21.0$; open circles: $21.0 < V \leq 22.0$; open triangles: $22.0 < V \leq 50\%$ completeness limit. The reddening vectors are shown as arrows; the effects of reddening on unreddened evolutionary tracks of an instantaneous burst stellar population (BC96, full drawn lines) are indicated by the dotted tracks. We have only included those sources that were not significantly affected by nearby neighbors or highly variable backgrounds.

5. Cluster luminosity profiles in close-up

In Fig. 2 we present the light profiles of the five brightest star cluster candidates in each field. These objects have sufficient S/N ratios and are relatively isolated, thus enabling us to follow the light profiles out to reasonably large radii.

Several cluster radial luminosity functions have recently been used in the literature, the simplest of them being a two-dimensional Gaussian. Alternatively, more complex models have been used, that are better representations of the true stellar light distribution in *globular* clusters. The most general of these is the mathematically convenient function of

Figure 2. Luminosity profiles for the 5 brightest star clusters in both B1 and B2. Columns 1 and 3: data points, superposed with the best-fitting Gaussian (short-dashed lines), modified Hubble ($\gamma = 2.0$, long-dashed lines), and $\gamma = 2.6$ profiles (Elson et al. 1987). Columns 2 and 4: ratios of data points to model fit – dots: Gaussian fits; crosses: modified Hubble profiles. The ratio for the $\gamma = 2.6$ (“Elson”) profiles is marginally to significantly reduced compared to the modified Hubble profile ($\gamma = 2.0$) fits.

surface brightness $\mu(r)$ as a function of radius r , proposed by Elson et al. (1987):

$$\mu(r) = \mu_0 \left(1 + (r/R_{\text{core}})^2 \right)^{-\gamma/2}, \quad (1)$$

which reduces to a modified Hubble law for $\gamma = 2$. In fact, Elson et al. (1987) found, for 10 rich star clusters in the LMC, that $2.2 \lesssim \gamma \lesssim 3.2$, with a median $\gamma = 2.6$.

From these figures, it is obvious that even though all three fitting functions may represent the inner profiles relatively well, the discrepancy between the results in the outer parts is a strong argument in favor of the more extended modified Hubble or $\gamma = 2.6$ (“Elson”) profiles.

Elson et al. (1987) try to explain the approximate power-law behavior of the LMC cluster profiles at large radii in terms of different star formation time scales. They argue that the observations probably favor slow star formation. Under these circumstances *and* by assuming a high star formation efficiency, relaxation of a sufficiently clumpy gaseous protocluster through clump-clump or clump-star two-body encounters may produce the observed power-law luminosity profiles.

Some of the star clusters show evidence for asymmetrical structure, which may mean that they contain subclumps, or have not yet reached dynamical equilibrium. A visual inspection of these clusters shows that they are noticeably elongated. In the case of these clusters in particular, we may be witnessing ongoing merging processes. However, to strengthen this suggestion, we will need spectroscopic follow-up observations. Similar subclustering has been observed in the super star clusters in NGC 1569 (O’Connell et al. 1994) and some of the rich LMC star clusters (e.g., Fischer et al. 1993).

54 \setlength\fbboxrule{.4pt}

```

1.3. TEXTHEIGHT AND TEXTWIDTH

These are the main reason for the existence of these files. For some stupid reason, $\text{\LaTeX}$ calculates `textwidth` out of `\paperwidth`. We did want to support letter paper, but our `\textwidth` is fixed, with the margins being calculated.

Presume `\textwidth` and `\marginparwidth` are set in the stylefile, or we're in trouble. The 2pc value is used to compensate for the 'dead' corners in most laserprinters.

Calculations are done 'AtBeginDocument' to allow changes made in the preamble and later on in the stylefile.

```

55 \newdimen\id@boxheight

52 \setlength\columnseprule{0pt}
53 \setlength\fbboxsep{3pt}
54 \setlength\fbboxrule{.4pt}

```

1.3. TEXTHEIGHT AND TEXTWIDTH

These are the main reason for the existence of these files. For some stupid reason, $\text{\LaTeX}$ calculates `textwidth` out of `\paperwidth`. We did want to support letter paper, but our `\textwidth` is fixed, with the margins being calculated.

Presume `\textwidth` and `\marginparwidth` are set in the stylefile, or we're in trouble. The 2pc value is used to compensate for the 'dead' corners in most laserprinters.

Calculations are done 'AtBeginDocument' to allow changes made in the preamble and later on in the stylefile.

```

55 \newdimen\id@boxheight

1.2. VARIOUS VALUES

Note that `\hoffset` and `\voffset` are both compensated. This makes the calculations below easier.

```

40 \setlength\hoffset{-1in}
41 \setlength\voffset{-1in}
42 \setlength\parindent {14\p@}
43 \setlength\headheight{12\p@}
44 \setlength\headsep    {12\p@}
45 \setlength\topskip    {10\p@}
46 \setlength\footskip   {27.5\p@}
47 \setlength\marginparsep{10pt}
48 \setlength\marginparpush{5\p@}
49 \setlength\maxdepth   {.5\topskip}
50 \setlength\@maxdepth\maxdepth
51 \setlength\columnsep{10pt}
52 \setlength\columnseprule{0pt}
53 \setlength\fbxsep{3pt}
54 \setlength\fbxrule{.4pt}

```

1.3. TEXTHEIGHT AND TEXTWIDTH

These are the main reason for the existence of these files. For some stupid reason, L^AT_EX calculates `textwidth` out of `\paperwidth`. We did want to support letter paper, but our `\textwidth` is fixed, with the margins being calculated.

Presume `\textwidth` and `\marginparwidth` are set in the stylefile, or we're in trouble. The 2pc value is used to compensate for the 'dead' corners in most laserprinters.

Calculations are done 'AtBeginDocument' to allow changes made in the preamble and later on in the stylefile.

```

55 \newdimen\id@boxheight
56 \AtBeginDocument{%
57   \setlength\@tempdima{\paperwidth}%
58   \addtolength\@tempdima{-\textwidth}%
59   \divide\@tempdima by 2
60   \setlength\@tempdimb\marginparwidth
61   \addtolength\@tempdimb\marginparsep
62   \addtolength\@tempdimb{2pc}%
63   \ifdim \@tempdima <\@tempdimb
64     \settopoint\@tempdimb
65     \GenericError{Pointsize}{Pointsize Error: Marginpars disabled}{}{You made

1.2. VARIOUS VALUES

Note that `\hoffset` and `\voffset` are both compensated. This makes the calculations below easier.

```

40 \setlength\hoffset{-1in}
41 \setlength\voffset{-1in}
42 \setlength\parindent {14\p@}
43 \setlength\headheight{12\p@}
44 \setlength\headsep {12\p@}
45 \setlength\topskip {10\p@}
46 \setlength\footskip {27.5\p@}
47 \setlength\marginparsep{10pt}
48 \setlength\marginparpush{5\p@}
49 \setlength\maxdepth {.5\topskip}
50 \setlength\@maxdepth\maxdepth
51 \setlength\columnsep{12pt}
52 \setlength\columnseprule{0pt}
53 \setlength\fbboxsep{3pt}
54 \setlength\fbboxrule{.4pt}

```

1.3. TEXTHEIGHT AND TEXTWIDTH

These are the main reason for the existence of these files. For some stupid reason, $\text{\LaTeX}$ calculates `textwidth` out of `\paperwidth`. We did want to support letter paper, but our `\textwidth` is fixed, with the margins being calculated.

Presume `\textwidth` and `\marginparwidth` are set in the stylefile, or we're in trouble. The `2pc` value is used to compensate for the 'dead' corners in most laserprinters.

Calculations are done 'AtBeginDocument' to allow changes made in the preamble and later on in the stylefile.

```

55 \newdimen\id@boxheight
56 \AtBeginDocument{%
57   \setlength\@tempdima{\paperwidth}%
58   \addtolength\@tempdima{-\textwidth}%

```

```

59 \divide\@tempdima by 2
60 \setlength\@tempdimb\marginparwidth
61 \addtolength\@tempdimb\marginparsep
62 \addtolength\@tempdimb{2pc}%
63 \ifdim \@tempdima <\@tempdimb
64   \@settopoint\@tempdimb
65   \GenericError{Pointsize}{Pointsize Error: Marginpars disabled}{}{You made
66   your \string\textwidth\space (\the\textwidth) and
67   \string\marginparwidth (\the\marginparwidth) too wide.\MessageBreak
68   The allowed value for margin space: (\the\@tempdima). Needed value:
69   (\the\@tempdimb).\MessageBreak
70   This is not enough,
71   so I will set \string\marginparwidth\space to Opt.\MessageBreak
72   Let's hope that fixes it.
73 }%
74 \marginparwidth \z@
75 \marginparsep \z@
76 \fi
77 \ifdim \@tempdima <2pc
78   \@tempdimb=\paperwidth
79   \advance\@tempdimb by -4pc
80   \@settopoint\@tempdimb
81   \GenericError{Pointsize}{Pointsize Error: Invalid sizes given}{}{You
82   made your \string\textwidth\space (\the\textwidth)
83   wider than the available total\MessageBreak
84   (Which is: \the\@tempdimb). Please press X and try again.
85 }%
86 \fi
87 \oddsidemargin \@tempdima
88 \evensidemargin \@tempdima

```

These calculations are a lot easier. \textheight should have been set already. This does not check for the correct placement of the identification line!!

```

89 \setlength\@tempdima{\paperheight}
90 \addtolength\@tempdima{-\footskip}
91 \addtolength\@tempdima{-\headheight}
92 \addtolength\@tempdima{-\headsep}
93 \setlength\@tempdimb{\@tempdima}
94 \addtolength\@tempdima{-\textheight}
95 \divide\@tempdima by 2
96 \ifdim \@tempdima <2pc
97   \advance\@tempdimb by -4pc
98   \@settopoint\@tempdimb

```

```

99      \GenericError{Pointsize}{Pointsize Error: Invalid sizes given}{}{You
100      made your \string\textheight\space (\the\textheight)
101      more than the available total.\MessageBreak
102      (Which is: \the\@tempdimb). Please press X and try again.
103      }%
104  \fi
105  \setlength\topmargin{\@tempdima}
106  \setlength\id@boxheight{\@tempdima}
107  \advance\id@boxheight by -2pc
108 }

109 \setlength\footnotesep{6.65\p@}
110 \setlength\skip\footins{12\p@ \@plus 4\p@ \@minus 2\p@}

```

1.4. LISTS

List default values

```

111 \setlength\partopsep{2\p@ \@plus 1\p@ \@minus 1\p@}
112 \setlength{\leftmargini}{2em}
113 \setlength{\leftmarginii}{2.2em}
114 \setlength{\leftmarginiii}{1.87em}
115 \setlength{\leftmarginiv}{1.7em}
116 \setlength{\leftmarginv}{1em}
117 \setlength{\leftmarginvi}{1em}
118 \setlength{\labelsep}{.4em}
119 \setlength{\labelwidth}{\leftmargini}
120 \addtolength{\labelwidth}{-\labelsep}

```

Note that lists below level 3 do nothing else then readjusting the `\labelwidth`. This results in very small labels for the inner lists.

```
